

1. A demodulation method for reproducing data from a signal received via a signal transmission path, said demodulation method comprising the steps of:

controlling an amplitude of the received
signal by AGC processing to be a predetermined level;

periodically conducting automatic equalization processing to the demodulated signal so as to adapt said demodulated signal to characteristics of said signal transmission path based on each training signal of said frame; and

2. A demodulation method according to claim 1, wherein, the time constant of said AGC processing is set so as to become longer than said updating repetition period of said automatic equalization processing.

3. A demodulation method according to claim 2,
wherein said time constant is so set that a change of a
control gain of said AGC processing becomes 0.5 dB or

less in one frame period.

4. A demodulation method according to claim 1, wherein setting a control gain of said AGC processing is conducted in synchronism with setting timing of updating value of tap coefficients of an automatic equalizer for performing and automatic equalization processing.

5. A demodulation method according to claim 1, wherein setting a control gain of said AGC processing is conducted every frame of the received signal.

6. A demodulation method according to claim 5, wherein setting said control gain of said AGC processing is conducted at head timing of each frame of said received signal.

7. A demodulation method according to claim 5, wherein setting said control gain of said AGC processing is conducted at every frame, and the value of said control gain is made constant until a subsequent frame is received.

8. A demodulation method according to claim 1, wherein said step of conducting automatic equalization processing comprises the steps of:

generating such correction coefficients as to make a received training signal coincide with a predetermined reference training signal; and

automatic equalizing said received signal based on said correction coefficients.

9. A demodulation method according to Claim 1,

10. A demodulation method according to claim 1,
wherein said received signal is a signal modulated by
using a multi-level amplitude modulation scheme.

```

        a signal input section for receiving a signal
including a series of frames each containing a training
signal for automatic equalization processing and a data
signal;

```

a demodulation circuit for conducting demodulation processing on an output signal of said AGC circuit; and

an automatic equalization circuit including a filter said automatic equalization circuit updating tap coefficients of said filter based on each training signal separated from the signal demodulated by said demodulation circuit, and conducting automatic equalization processing so as to adapt said demodulated signal to characteristics of the signal transmission

path,

wherein values of a time constant of said AGC circuit and an updating repetition period of said automatic equalization circuit are set so as to have a predetermined relation.

12. A demodulation apparatus according to claim 11, wherein said AGC circuit comprises:

a variable gain amplifier for receiving and amplifying the received signal;

a power calculator for calculating power of received signal from an output of said variable gain amplifier; and

a gain setting unit for setting a gain of said variable gain amplifier, and

the gain control time constant of said variable gain amplifier being set so as to become longer than said updating repetition period of said tap coefficients.

13. A demodulation apparatus according to claim 12, wherein said AGC circuit is set so as to cause a change of the gain of said variable gain amplifier to become 0.5 dB or less in one frame period.

14. A demodulation apparatus according to claim 11, wherein said AGC circuit comprises:

a variable gain amplifier for receiving and amplifying the received signal;

a power calculator for calculating power of the received signal from an output of said variable

gain amplifier;

a gain setting unit for setting a gain of said variable gain amplifier; and

means for causing the setting of the gain of said variable gain amplifier conducted by said gain setting unit to be carried out in synchronism with setting timing of updating values of the tap coefficients in said automatic equalization circuit.

15. A demodulation apparatus according to claim 11, wherein said AGC circuit comprises:

a variable gain amplifier for receiving and amplifying the received signal;

a power calculator for calculating power of the received signal from an output of said variable gain amplifier;

a gain setting unit for setting a gain of said variable gain amplifier; and

means for causing the setting of the gain of said variable gain amplifier conducted by said gain setting unit to be carried out every frame of said received signal.

16. A demodulation apparatus according to claim 15, wherein

said automatic equalization circuit comprises means for generating a signal that corresponds to head timing of each frame of said received signal, and

said gain setting unit conducts setting of the gain of said variable gain amplifier at timing of

the signal that corresponds to head timing of each frame of said received signal.

17. A demodulation apparatus according to claim 15, wherein

said automatic equalization circuit comprises means for generating a signal that corresponds to head timing of each frame of the received signal, and

said gain setting unit conducts setting of the gain of said variable gain amplifier every signal that corresponds to head timing of each frame of the received signal, and said gain setting unit does not update a value of said gain until a signal that corresponds to next head timing is input.

18. A demodulation apparatus according to claim 11, wherein said automatic equalization circuit comprises:

means for detecting a training signal from said received signal;

a first automatic equalizer for training signal;

a second automatic equalizer for data signal;

means for generating such correction coefficients as to make the detected training signal coincide with a predetermined reference training signal; and

means for modifying the tap coefficients of said second automatic equalizer with the correction coefficients.

19. A demodulation apparatus according to claim 11, wherein said signal input section receives a signal transmitted from an antenna switched over at timing synchronized to the frames on a transmission side having a plurality of transmission antennas.

20. A demodulation apparatus according to claim 11, further comprising an identifying unit for reproducing data from a data signal output from said automatic equalization circuit.
